

## Algorithmics II (H) Exam April / May 2023 – Solutions

1. (a) (i) The following operations would take place involving the temporary convex hull, assuming that  $p_7$  is chosen as the pivot:

- |                 |                     |
|-----------------|---------------------|
| 1. add $p_7$    | 10. add $p_{11}$    |
| 2. add $p_{12}$ | 11. add $p_1$       |
| 3. add $p_8$    | 12. remove $p_1$    |
| 4. remove $p_8$ | 13. add $p_5$       |
| 5. add $p_3$    | 14. add $p_6$       |
| 6. add $p_9$    | 15. remove $p_6$    |
| 7. add $p_4$    | 16. add $p_{10}$    |
| 8. remove $p_4$ | 17. remove $p_{10}$ |
| 9. remove $p_9$ | 18. add $p_2$       |

- (ii) The convex hull comprises  $p_7, p_{12}, p_3, p_{11}, p_5, p_2$ .

- (b) (i) Let  $t$  be the predecessor of  $q$  on the temporary convex hull. We must make a “left turn” at  $q$  when travelling from  $t$  to  $q$  to  $r$ , since  $t$  was discovered before  $q$  during the anticlockwise scan phase and  $r$  has a larger  $x$ -coordinate than  $q$ .
- (ii) Let  $s$  be the second point added to the temporary convex hull (after  $r$ ). We must make a “left turn” at  $r$  when travelling from  $q$  to  $r$  to  $s$ , since  $s$  was discovered before  $q$  during the anticlockwise scan phase and  $r$  has a larger  $x$ -coordinate than each of  $q$  and  $s$ .

2. (a) The recursive method `recExtent` can be completed as follows:

```

recExtent(int i, int j, int I, int J)
{
    if (S(i,j)==0)
        output "X: ["+(i+1)+", "+I+"]   Y: ["+(j+1)+", "+J+"] ";
    else if (X(i)==Y(j))
        recExtent(i-1,j-1,I,J);
    else
    {
        if (S(i,j)==S(i-1,j-1)-1)
            recExtent(i-1,j-1,I,J);
        if (S(i,j)==S(i-1,j)-1)
            recExtent(i-1,j,I,J);
        if (S(i,j)==S(i,j-1)-1)
            recExtent(i,j-1,I,J);
    }
}

```

- (b) An optimal alignment of (the unique) highest scoring local similarity of  $X$  and  $Y$  is as follows:

<b>G</b>	<b>C</b>	<b>A</b>	<b>T</b>	<b>A</b>	<b>T</b>	<b>C</b>	<b>G</b>
<b>m</b>	<b>m</b>	<b>m</b>	<b>s</b>	<b>m</b>	<b>d</b>	<b>m</b>	<b>m</b>
<b>G</b>	<b>C</b>	<b>A</b>	<b>G</b>	<b>A</b>		<b>C</b>	<b>G</b>

3. (a) The remaining preference lists upon termination of the algorithm are as follows:

$s_1$ :	$\ell_4$	$\ell_1$	$\ell_2$	$\ell_3$	$\ell_1$ :	$s_3$	$s_4$	$s_1$	$s_2$
$s_2$ :	$\ell_1$				$\ell_2$ :	$s_4$	$s_1$	$s_3$	
$s_3$ :	$\ell_2$	$\ell_1$			$\ell_3$ :	$s_1$	$s_4$		
$s_4$ :	$\ell_3$	$\ell_1$	$\ell_2$		$\ell_4$ :	$s_1$			
Students' preferences					Lecturers' preferences				

- (b) Clearly  $M$  is a matching, since upon termination, each student is assigned exactly one lecturer and each lecturer is assigned at most one student. Suppose that  $s$  prefers  $\ell$  to their partner in  $M$ . Then  $\ell$  was deleted from  $s$ 's list during the algorithm's execution, so  $s$  was deleted from  $\ell$ 's list. That happened because some student  $s'$  became matched to  $\ell$ , where  $\ell$  prefers  $s'$  to  $s$ . Hence  $\ell$ 's partner in  $M$  must be  $s'$  or better, and hence better than  $s$ . Thus  $(s, \ell)$  does not block  $M$ , and since  $(s, \ell)$  was arbitrary,  $M$  must be stable.
4. (a) Given an instance  $I$  of PARTITION comprising integers  $x_1, x_2, \dots, x_n$ , create the following instance  $I'$  of JSSP. Let  $J = \{j_1, j_2, \dots, j_n\}$  and create  $n$  identical machines. Let  $t_i = x_i$  for all  $i$  ( $1 \leq i \leq n$ ) and let  $T = \frac{1}{2} \sum_{i \in N} x_i$ .

Now suppose that  $A$  is an approximation algorithm for JSSP with a performance guarantee  $< 3/2$ .

Suppose firstly that  $I$  admits a partition. Then  $m^*(I') = 2$ , so  $A$  gives an assignment of jobs to machines using  $< 3/2 m^*(I')$  machines, i.e., using 2 machines.

Conversely suppose that  $I$  does not admit a partition. Then  $m^*(I') \geq 3$ . Hence  $A$  gives an assignment of jobs to machines using at least 3 machines.

Thus the existence of  $A$  gives a polynomial-time algorithm for PARTITION, which is a contradiction unless  $P=NP$ .

- (b) Process the jobs in some order. For each job  $j$ , if some machine  $m$  already in use has enough spare time to accommodate  $j$ , assign  $j$  to  $m$ , otherwise assign  $j$  to a new machine.
- (c) JSSP does have an approximation algorithm with performance guarantee  $3/2$ . This is because JSSP is equivalent to the Minimum Bin Packing problem (which is approximable within  $3/2$  using the First Fit Decreasing algorithm, though this reasoning was not required as part of the answer).
