# What Is a Program?

- Usually, one or more algorithms written in a programming language that can be translated to run on a real machine
- We sometimes call programs *software*

# What Is a Programming Language?

- A programming language is somewhat like a **natural language**, but with a very limited set of statements and strict syntax rules.
- Has statements to implement sequential, conditional and iterative processing - algorithms
- Examples: FORTRAN, COBOL, Lisp, Basic, Pascal, C, C++, Java, C#, Python, ...

# Programming Languages: Types

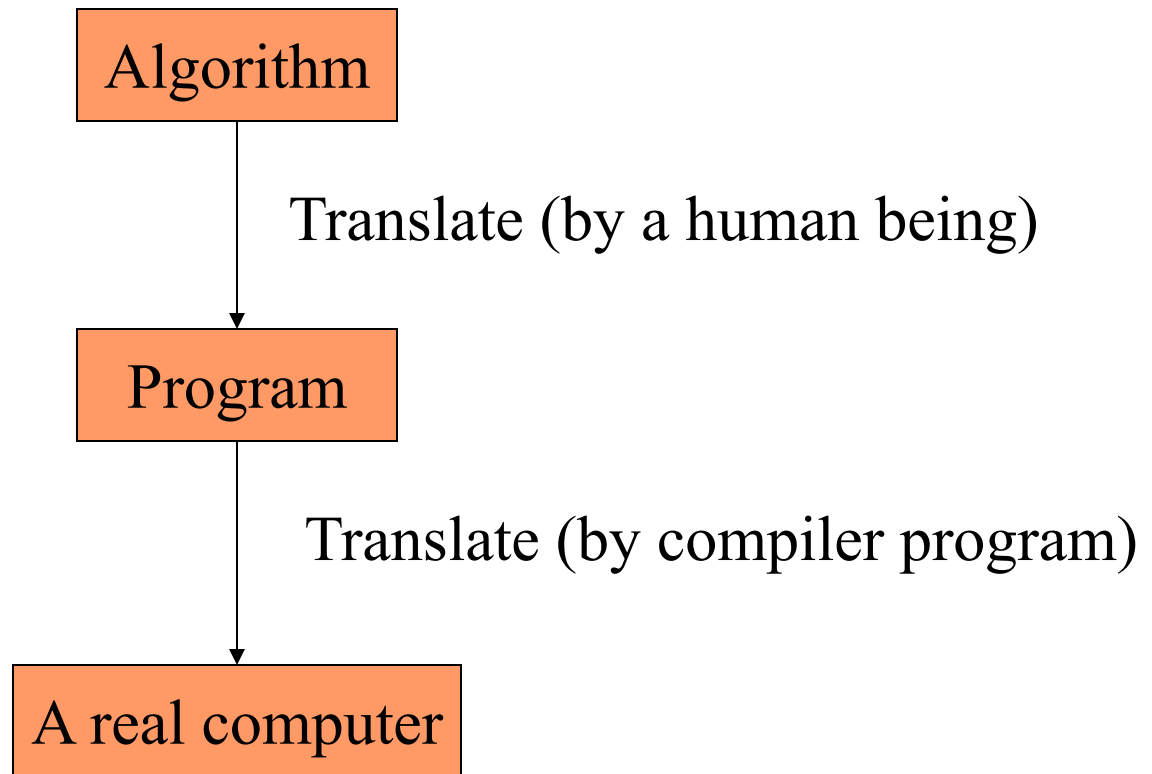

# Programming Languages: Types

- Compiled
- Interpreted

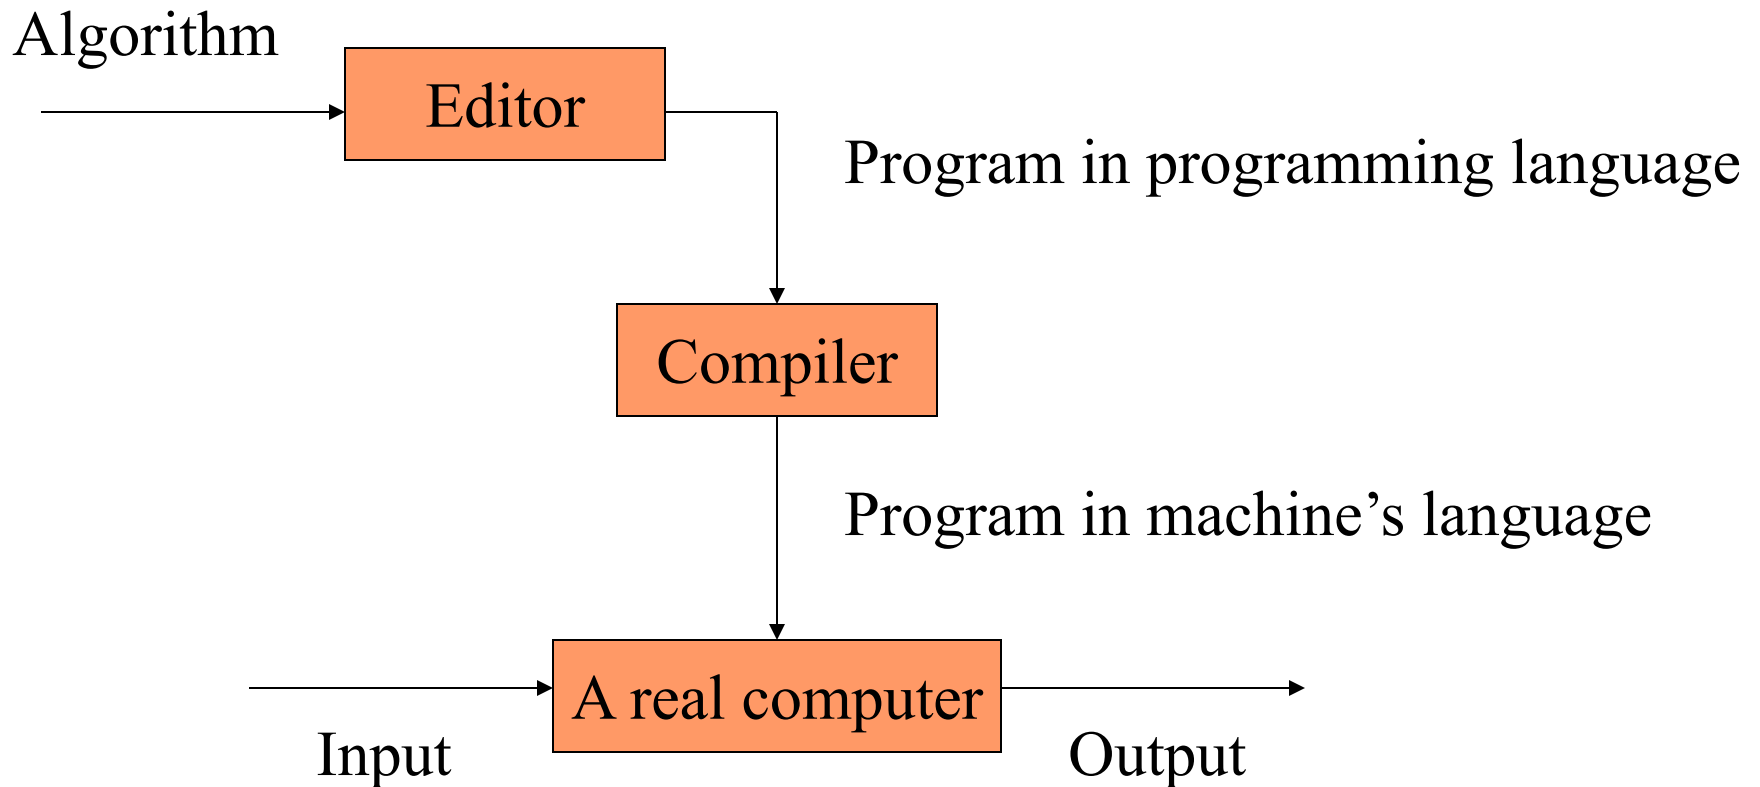

# Compiler

- A *compiler* is a program that converts a program written in a programming language into a program in the native language, called *machine language*, of the machine that is to execute the program.

# From Algorithms to Hardware (with compiler)

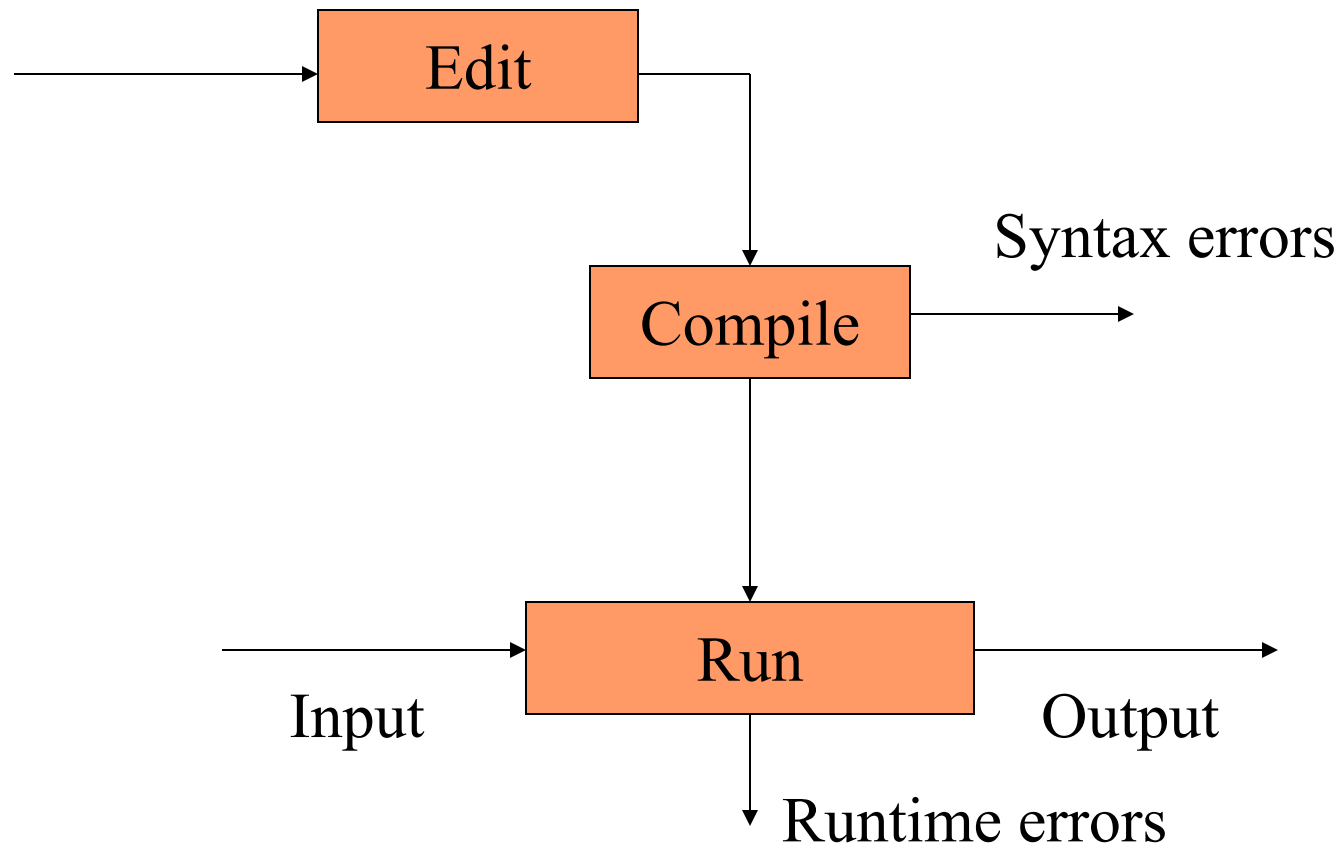

# The Program Development Process (Data Flow)

# The Program Development Process (Control Flow)

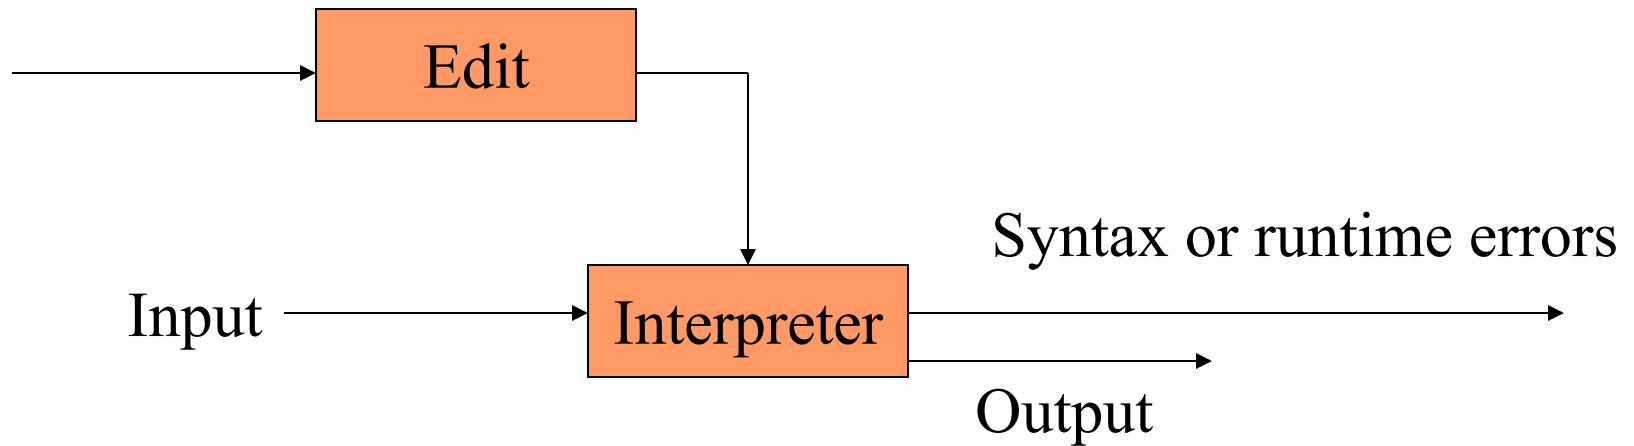

# Three kinds of errors

- *Syntax error* : Some statement in the program is not a legal statement in the language.
- *Runtime error* : An error occurs while the program is executing, causing the program to terminate (divide by zero, etc.)
- *Logic error* : The program executes to completion, but gives incorrect results.

# Interpreter

- An alternative to a compiler is a program called an *interpreter*. Rather than convert our program to the language of the computer, the interpreter takes our program one statement at a time and executes a corresponding set of machine instructions.

# Interpreter

# Python

- Python uses an interpreter. Not only can we write **complete** programs, we can work with the **interpreter** in a statement by statement mode enabling us to experiment quite easily.
- Python is especially good for our purposes in that it does not have a lot of “**overhead**” before getting started.
- It is easy to jump in and experiment with Python in an interactive fashion.

# Python

- Python uses an interpreter. Not only can we write **complete** programs, we can work with the **interpreter** in a statement by statement mode enabling us to experiment quite easily.
- Python is especially good for our purposes in that it does not have a lot of “**overhead**” before getting started.
- It is easy to jump in and experiment with Python in an interactive fashion.

→ Python is OO

# Language terminology

- **Syntax:** The formal rules for legal statements in the language.
- **Semantics:** The meaning of the statements - what happens when the statement is executed.

# Three major control constructs of programming

- **Sequential:** Simply do steps one after the other in order they are listed.
- **Conditional:** Decide which statement to do next based on some true/false test.
- **Iterative:** A set of statements is repeated over and over until some condition is met.

# Sequential Operations

## “Atomic”

- Input
- Computation
- Output

# The Basic Pattern

- Most of our programs will use the basic pattern of
  - Get some user input
  - Perform some algorithm on the input
  - Provide results as output

# Identifiers

- *Identifiers* are names of various program elements in the code that uniquely identify the elements. They are the names of things like variables or functions to be performed. They're specified by the programmer and should have names that indicate their purpose.
- In Python, identifiers
  - Are made of **letters**, **digits** and **underscores**
  - Must **begin** with a letter or an underscore
  - Examples: temperature, myPayrate, score2

# Keywords

- *Keywords* are reserved words that have special meaning in the Python language. Because they are reserved, they can not be used as identifiers. Examples of keywords are *if, while, class, import*.

# Variables in Python

- A variable has
  - A name – identifier
  - A data type - int, float, str, etc.
  - Storage space sufficient for the type.

# Numeric Data Types

- **int**

This type is for whole numbers, positive or negative. Examples: 23, -1756

- **float**

This type is for numbers with possible fraction parts. Examples: 23.0, -14.561

# Integer operators

The operations for integers are:

+ for addition

- for subtraction

\* for multiplication

/ for integer division: The result of  $14/5$  is 2

% for remainder: The result of  $14 \% 5$  is 4

- \*, /, % take precedence over +, -  
 $x + y * z$  will do  $y * z$  first
- Use parentheses to dictate order you want.  
 $(x + y) * z$  will do  $x + y$  first.

# Integer Expressions

- Integer expressions are formed using
  - Integer Constants
  - Integer Variables
  - Integer Operators
  - Parentheses

# Python Assignment Statements

- In Python, = is called the *assignment operator* and an *assignment statement* has the form

`<variable> = <expression>`

- Here
  - `<variable>` would be replaced by an actual variable
  - `<expression>` would be replaced by an expression
- Python:            `age = 19`

# Python Assignment Statement

- **Syntax:** `<variable> = <expression>`
  - Note that variable is on left
- **Semantics:**
  - Compute value of expression
  - Store this as new value of the variable
- **Example:** `Pay = PayRate * Hours`

# Assignment Example

**Before**

**X**

3

**Y**

5

**Z**

12

**Execute**

$$Z = X * 3 + Z / Y$$

**After**

**X**

3

**Y**

5

**Z**

11

# Comments in a Program

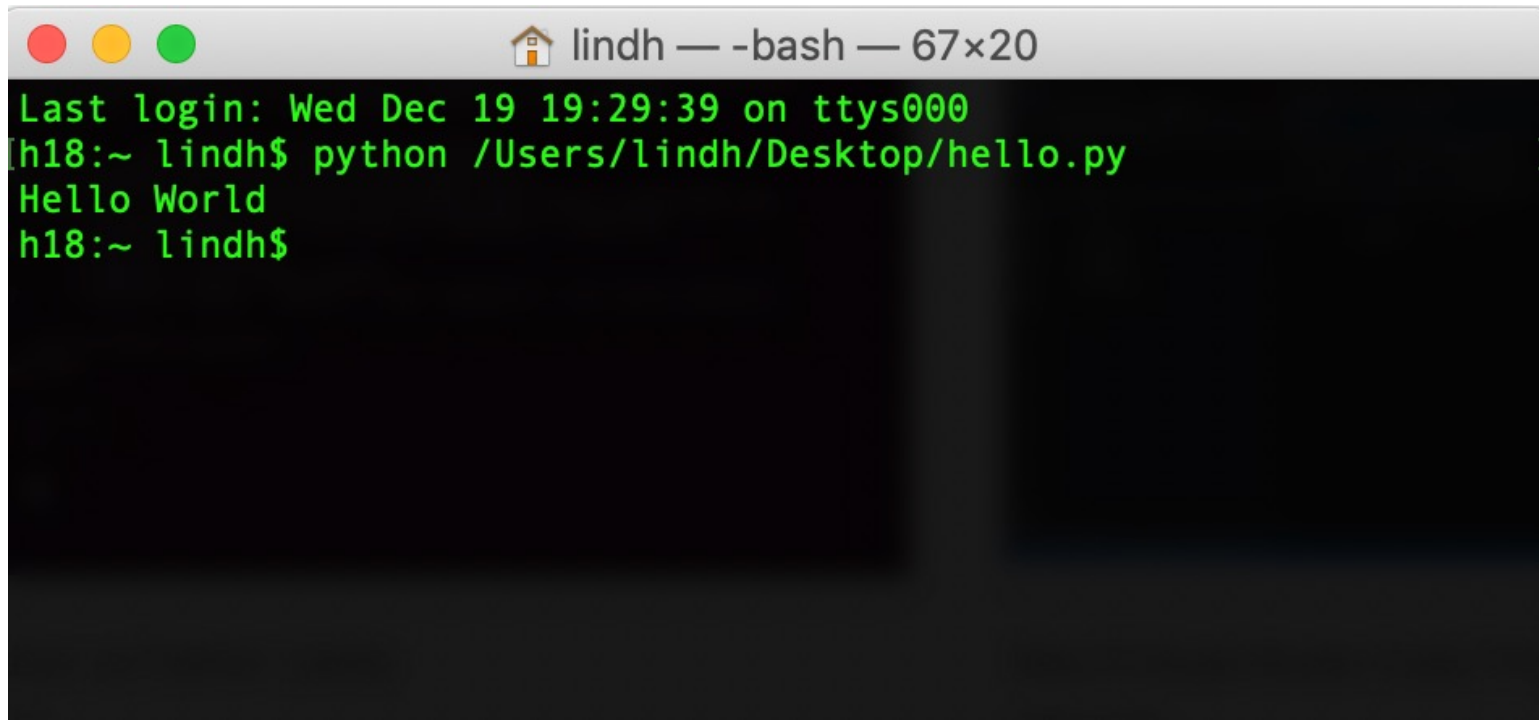

- Often we want to put some documentation in our program. These are comments for explanation, but not executed by the computer.
- If we have `#` anywhere on a line, everything following this on the line is a comment – ignored
- Use of “
- Good source codes always include comments

# Preparation of Python Environments

- Many options
  - Python 3 interpreter from the official site
    - Latest version: Python 3.10
    - <https://www.python.org/downloads/>
  - Anaconda
    - Python interpreter with a lot of modules for data analysis, data plotting, etc.
    - <https://www.anaconda.com/download/>
  - You can also use online environments like **Google Colaboratory** (Recommended for beginners)

# How to Execute Python Programs (1)

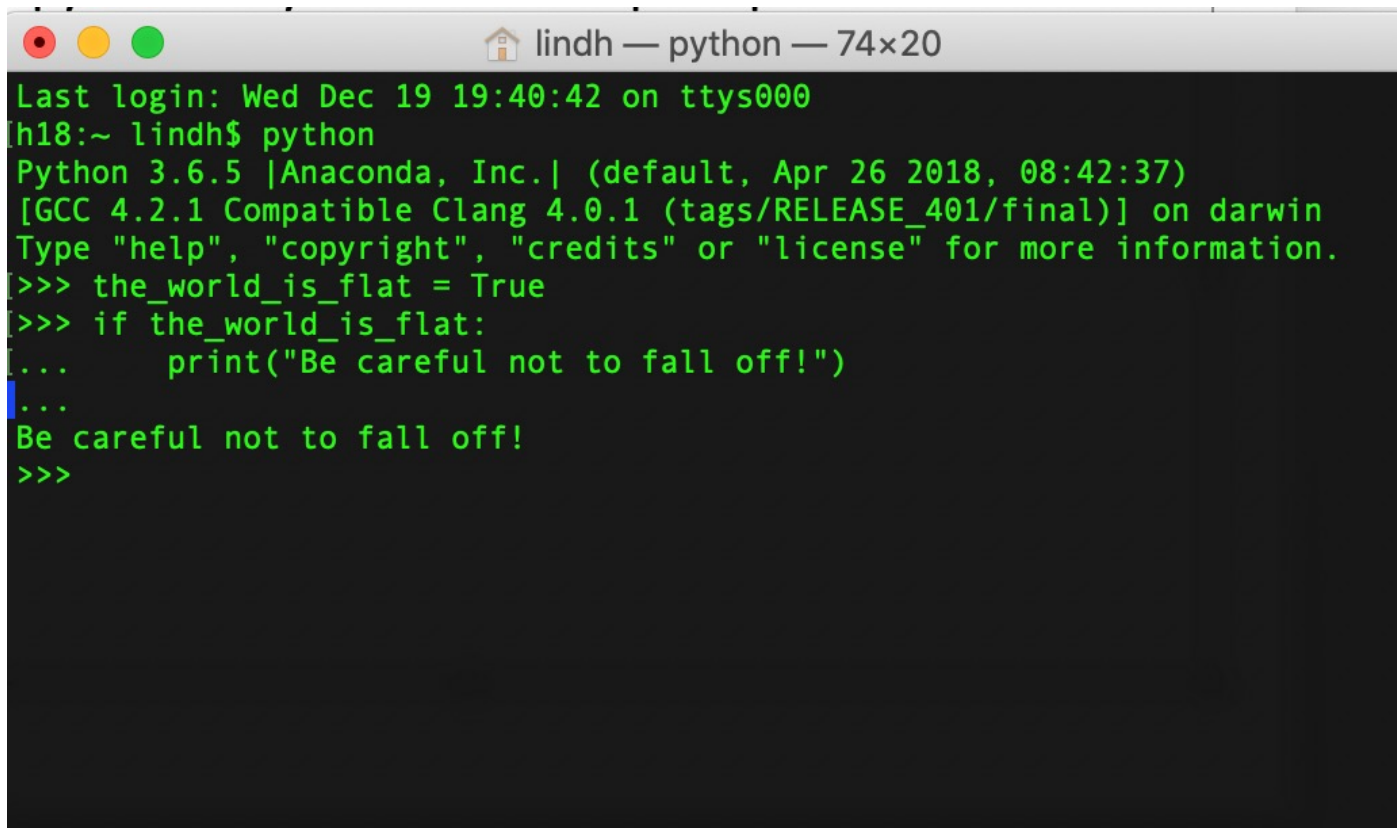

- Command prompt in Windows (or Terminal in MAC OS)
  - C:\Users\lindh> python C:\PBI\hello.py

A screenshot of a macOS Terminal window. The title bar at the top shows three colored window control buttons (red, yellow, green) on the left, a home icon followed by the text 'lindh — -bash — 67x20' in the center, and a dark gray background on the right. The terminal content is displayed in green text on a black background. It shows the last login time as 'Wed Dec 19 19:29:39 on ttys000'. The user 'h18' is at the prompt '~ lindh\$' and has entered the command 'python /Users/lindh/Desktop/hello.py'. The output of the program is 'Hello World', followed by the prompt 'h18:~ lindh\$' on a new line.

```
lindh — -bash — 67x20
Last login: Wed Dec 19 19:29:39 on ttys000
h18:~ lindh$ python /Users/lindh/Desktop/hello.py
Hello World
h18:~ lindh$
```

# How to Execute Python Programs (2)

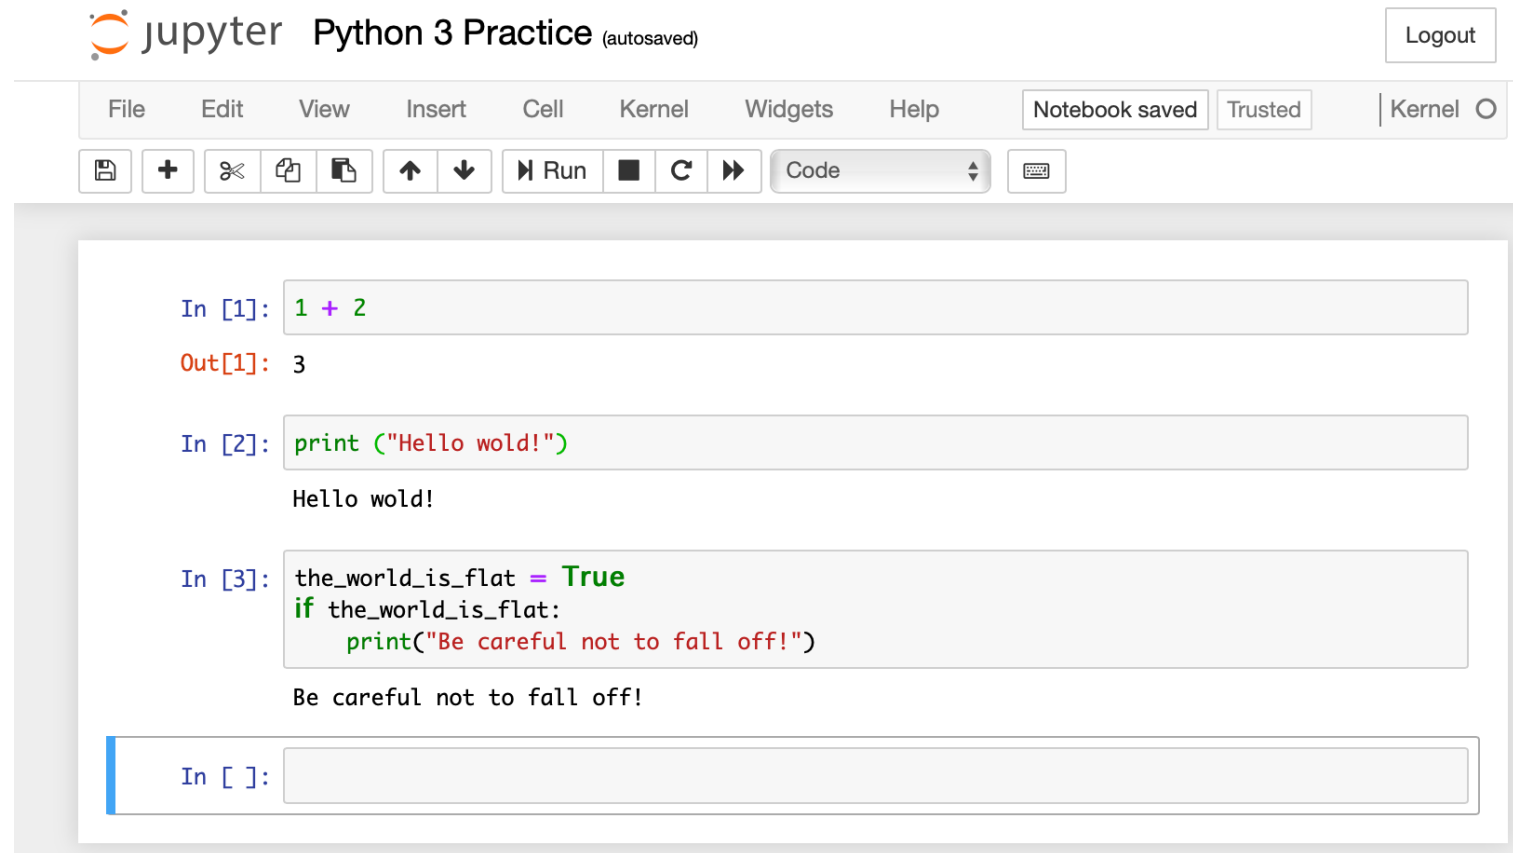

- Python Interactive Mode
  - Input “python” in your command prompt or terminal

A screenshot of a terminal window titled "lindh — python — 74x20". The terminal shows the output of running the "python" command. It displays the last login time, the Python version (3.6.5), the distribution (Anaconda, Inc.), and the compiler (GCC 4.2.1). It then shows an interactive session where the user defines a variable "the\_world\_is\_flat" as True, checks if it is True, and prints the message "Be careful not to fall off!".

```
lindh — python — 74x20
Last login: Wed Dec 19 19:40:42 on ttys000
[h18:~ lindh$ python
Python 3.6.5 |Anaconda, Inc.| (default, Apr 26 2018, 08:42:37)
[GCC 4.2.1 Compatible Clang 4.0.1 (tags/RELEASE_401/final)] on darwin
Type "help", "copyright", "credits" or "license" for more information.
>>> the_world_is_flat = True
>>> if the_world_is_flat:
...     print("Be careful not to fall off!")
...
Be careful not to fall off!
>>>
```

# How to Execute Python Programs (3)

- Jupyter Notebook (Recommended)
  - Can be started from Anaconda or Google Colaboratory

# Python 3 Tutorials

- Suggested Python 3 Tutorials
  - A Byte of Python
    - <https://python.swaroopch.com>
  - Official Python 3 Documentation
    - <https://docs.python.org/3/>
    - Tutorial:  
<https://docs.python.org/3.10/tutorial/index.html>
- Read until *Data Structures* and you will get most of the necessary knowledge for your assignment 07

# How to Learn Programming Efficiently

- Learn by examples
  - Type the examples by yourself
  - Execute the examples
  - Read line by line and analyze the execution result
  - Create some errors manually and understand the error message during execution
